Frogs, toads and newts are all amphibians and spend part of the year on land and part of the year in water but always return to the water to breed and lay eggs. A frog lays eggs as frogspawn which change into tadpoles, then froglets, then adult frogs. This process of change is called metamorphosis. All UK amphibians spend the cold winter in a deep sleep or hibernation.

Toads have warts and can ooze a poison from their bodies but are harmless to us humans and are toadally beautiful (we think) - they are sadly becoming much less common. Only newts have tails as adults, frogs and toads lose their tails as they change into fully grown adults.
